Gradient Descent

Unconstrained Optimization

Setting

Objective function $f : \mathbf{R}^d \rightarrow \mathbf{R}$ is *differentiable*.

Want to find

$$x^* = \arg \min_{x \in \mathbf{R}^d} f(x)$$

The Gradient

- Let $f : \mathbf{R}^d \rightarrow \mathbf{R}$ be differentiable at $x_0 \in \mathbf{R}^d$.
- The **gradient** of f at the point x_0 , denoted $\nabla_x f(x_0)$, is the direction to move in for the **fastest increase** in $f(x)$, when starting from x_0 .

Figure A.111 from Newtonian Dynamics, by Richard Fitzpatrick.

Gradient Descent

Gradient Descent

- Initialize $x = 0$
- repeat
 - $x \leftarrow x - \underbrace{\eta}_{\text{step size}} \nabla f(x)$
- until stopping criterion satisfied

Gradient Descent Path

Gradient Descent: Step Size

- A fixed step size will work, eventually, as long as it's small enough (roughly - details to come)
 - Too fast, may diverge
 - In practice, try several fixed step sizes
- Intuition on when to take big steps and when to take small steps?

Convergence Theorem for Fixed Step Size

Theorem

Suppose $f : \mathbf{R}^d \rightarrow \mathbf{R}$ is convex and differentiable, and ∇f is **Lipschitz continuous** with constant $L > 0$, i.e.

$$\|\nabla f(x) - \nabla f(x')\| \leq L\|x - x'\|$$

for for any $x, x' \in \mathbf{R}^d$. Then gradient descent with fixed step size $\eta \leq 1/L$ **converges**. In particular,

$$f(x^{(k)}) - f(x^*) \leq \frac{\|x^{(0)} - x^*\|^2}{2\eta k}.$$

Step Size: Practical Note

- Although a $1/L$ step-size guarantees convergence,
 - it may be **much slower** than necessary.
- May be worth trying larger step sizes as well.
- But math tells us, no need for anything smaller.

Gradient Descent: When to Stop?

- Wait until $\|\nabla f(x)\|_2 \leq \varepsilon$, for some ε of your choosing.
 - (Recall $\nabla f(x) = 0$ at minimum.)
- For learning setting,
 - evaluate performance on validation data as you go
 - stop when not improving, or getting worse
